## Health Risk Assessment Background and Modeling Data

# 1. Health Risk Assessment

---

## 1.1 CONSTRUCTION HEALTH RISK ASSESSMENT

Soltage, LLC (the project applicant) proposes to construct, install, operate, and maintain a solar photovoltaic (PV) facility located at West Grant Line Road and Great Valley Parkway in eastern unincorporated Alameda County. The approximately 23.07-acre proposed project site is currently undeveloped and is bounded by Grant Line Road to the south and vacant lots to the north, east, and west. The following provides the background methodology used for the construction health risk assessment for the proposed project.

The latest version of the Bay Area Air Quality Management District (BAAQMD) CEQA Air Quality Guidelines requires projects to evaluate the impacts of construction activities on sensitive receptors (BAAQMD, 2017). Project construction is anticipated to take place starting at the beginning of July 2022 and be completed by August 2022 (approximately 47 workdays). The nearest sensitive receptors to the project site include the single-family residences to the southeast. Additional sensitive receptors within 1,000 feet of the site are single family residences to the east beyond Great Valley Parkway and preschool children at Sunshine Shwetha Preschool and Daycare, approximately 1,000 feet to the northeast. The BAAQMD has developed *Screening Tables for Air Toxics Evaluation During Construction* (2017) that evaluate construction-related health risks associated with residential, commercial, and industrial projects. According to the screening tables, the receptors are closer than the distance of 200 meters (656 feet) that would screen out potential health risks and, therefore, could be potentially impacted from the proposed construction activities. As a result, a site-specific construction health risk assessment (HRA) has been prepared for the proposed project. This HRA considers the health impact to off-site sensitive receptors (i.e., the nearby residences and children at the preschool) from construction emissions at the project site, including diesel equipment exhaust (diesel particulate matter or DPM) and particulate matter less than 2.5 microns ( $PM_{2.5}$ ).

It should be noted that these health impacts are based on conservative (i.e., health protective) assumptions. The United States Environmental Protection Agency (USEPA, 2005) and the Office of Environmental Health Hazard Assessment (OEHHA, 2015) note that conservative assumptions used in a risk assessment are intended to ensure that the estimated risks do not underestimate the actual risks. Therefore, the estimated risks may not necessarily represent actual risks experienced by populations at or near a site. The use of conservative assumptions tends to produce upper-bound estimates of exposure and thus risk.

For residential-based receptors, the following conservative assumptions were used:

- It was assumed that maximum-exposed off-site residential receptors (both children and adults) stood outdoors and are subject to DPM at their residence for 8 hours per day, and approximately 260 construction days per year. In reality, California residents typically will spend on average 2 hours per day outdoors at their residences (USEPA, 2011). This would result in lower exposures to construction related DPM emissions and lower estimated risk values.

- The calculated risk for infants from third trimester to age 2 is multiplied by a factor of 10 to account for early life exposure and uncertainty in child versus adult exposure impacts (OEHHA, 2015).

For preschool children, the following conservative assumptions were used:

- It was assumed that maximum exposed receptor (preschool child) stood outside and are subject to DPM for 8 hours per weekday and approximately 260 construction days per year.
- The calculated risk for children age 0 to age 2 is multiplied by a factor of 10 to account for early life exposure and uncertainty in child versus adult exposure impacts (OEHHA, 2015).

## 1.2 METHODOLOGY AND SIGNIFICANCE THRESHOLDS

For this HRA, the BAAQMD significance thresholds were deemed to be appropriate and the thresholds that were used for this project are shown below:

- Excess cancer risk of more than 10 in a million
- Non-cancer hazard index (chronic or acute) greater than 1.0
- Incremental increase in average annual PM<sub>2.5</sub> concentration of greater than 0.3 µg/m<sup>3</sup>

The methodology used in this HRA is consistent with the following BAAQMD and the OEHHA guidance documents:

- BAAQMD, 2017. *California Environmental Quality Act (CEQA) Air Quality Guidelines*. May 2017.
- BAAQMD, 2016. *Planning Healthy Places*. May 2016.
- BAAQMD, 2010. *Screening Tables for Air Toxics Evaluation During Construction*. May 2010.
- BAAQMD, 2012. *Recommended Methods for Screening and Modeling Local Risks and Hazards*. Version 3.0. May 2012.
- OEHHA. 2015. *Air Toxics Hot Spots Program Guidance Manual for the Preparation of Health Risk Assessments*. February 2015.

Potential exposures to DPM and PM<sub>2.5</sub> from proposed project construction were evaluated for off-site sensitive receptors in close proximity to the site. Pollutant concentrations were estimated using an air dispersion model, and excess lifetime cancer risks and chronic non-cancer hazard indexes were calculated. These risks were then compared to the significance thresholds adopted for this HRA.

## **1.3 CONSTRUCTION EMISSIONS**

Construction emissions were calculated as average daily emissions in pounds per day, using the proposed construction schedule and the latest version of California Emissions Estimation Model, known as CalEEMod Version 2020.4 (CAPCOA, 2021). DPM emissions were based on the CalEEMod construction runs, using annual exhaust PM<sub>10</sub> construction emissions presented in pounds (lbs) per day. The PM<sub>2.5</sub> emissions were taken from the CalEEMod output for exhaust PM<sub>2.5</sub> also presented in lbs per day.

The project was assumed to take place over 2 months (47 workdays) from July 2022 to August 2022. The average daily emission rates from construction equipment used during the proposed project were determined by dividing the annual average emissions for each construction year by the number of construction days per year for each calendar year of construction (i.e., 2022). The off-site hauling emission rates were adjusted to evaluate localized emissions from the 0.39-mile haul route within 1,000 feet of the project site. The CalEEMod construction emissions output and emission rate calculations are provided in Appendix A of the HRA.

## **1.4 DISPERSION MODELING**

Air quality modeling was performed using the AERMOD atmospheric dispersion model to assess the impact of emitted compounds on sensitive receptors near the project. The model is a steady state Gaussian plume model and is an approved model by BAAQMD for estimating ground level impacts from point and fugitive sources in simple and complex terrain. The on-site construction emissions for the project were modeled as poly-area sources. The off-site mobile sources were modeled as adjacent line volume sources. The model requires additional input parameters, including chemical emission data and local meteorology. Inputs for the construction emission rates are those described in Section 1.3. Meteorological data obtained from the BAAQMD for the nearest representative meteorological station (Livermore Municipal Airport) with the five latest available years (2009 to 2013) of record were used to represent local weather conditions and prevailing winds.

The modeling analysis also considered the spatial distribution and elevation of each emitting source in relation to the sensitive receptors. To accommodate the model's Cartesian grid format, direction-dependent calculations were obtained by identifying the Universal Transverse Mercator (UTM) coordinates for each source location. In addition, digital elevation model (DEM) data for the area were obtained and included in the model runs to account for complex terrain. An emission release height of 4.15 meters was used as representative of the stack exhaust height for off-road construction equipment and diesel truck traffic, and an initial vertical dispersion parameter of 1.93 m was used, per California Air Resources Board (CARB) guidance (2000).

To determine contaminant impacts during construction hours, the model's Season-Hour-Day (HRDOW) scalar option was invoked to predict flagpole-level concentrations (1.5 m for ground floor receptors; 6.1 m for 2<sup>nd</sup> floor receptors) for construction emissions generated between the hours of 7:00 AM and 4:00 PM with a 1-hour lunch break. In addition, a scalar factor was applied to the risk calculations to account for the number of days receptors are exposed to construction emissions per year.

A unit emission rate of 1 gram per second was used for all modeling runs. The unit emission rates were proportioned over the poly-area sources for on-site construction emissions and divided between the volume sources for off-site hauling emissions. The maximum modeled concentrations from the output files were then multiplied by the emission rates calculated in Appendix A to obtain the maximum flagpole-level concentrations at the off-site maximum exposed receptors (MER). The air dispersion modeling predicted the off-site MER is a single-family residence southeast of the site. The MER location is the receptor location associated with the maximum predicted AERMOD concentrations from the on-site emission source. The calculated on-site emission rates are approximately 4 orders of magnitude higher than the calculated off-site emission rates (see Appendix A). Therefore, the maximum concentrations associated with the on-site emission sources produce the highest overall ground-level MER concentrations and, consequently, highest calculated health risks.

The air dispersion model output for the emission sources is presented in Appendix B. The model output DPM and PM<sub>2.5</sub> concentrations from the construction emission sources are provided in Appendix C.

## 1.5 RISK CHARACTERIZATION

### 1.5.1 Carcinogenic Chemical Risk

A threshold of ten in a million ( $10 \times 10^{-6}$ ) has been established as a level posing no significant risk for exposures to carcinogens. Health risks associated with exposure to carcinogenic compounds can be defined in terms of the probability of developing cancer as a result of exposure to a chemical at a given concentration. The cancer risk probability is determined by multiplying the chemical's annual concentration by its cancer potency factor (CPF), a measure of the carcinogenic potential of a chemical when a dose is received through the inhalation pathway. It is an upper-limit estimate of the probability of contracting cancer as a result of continuous exposure to an ambient concentration of one microgram per cubic meter ( $\mu\text{g}/\text{m}^3$ ) over a lifetime of 70 years.

Recent guidance from OEHHA recommends a refinement to the standard point estimate approach with the use of age-specific breathing rates and age sensitivity factors (ASFs) to assess risk for susceptible subpopulations such as children. For the inhalation pathway, the procedure requires the incorporation of several discrete variates to effectively quantify dose for each age group. Once determined, contaminant dose is multiplied by the cancer potency factor in units of inverse dose expressed in milligrams per kilogram per day ( $\text{mg}/\text{kg}/\text{day}$ )<sup>-1</sup> to derive the cancer risk estimate. Therefore, to accommodate the unique exposures associated with the sensitive receptors, the following dose algorithm was used.

$$\text{Dose}_{\text{AIR,per age group}} = (\text{C}_{\text{air}} \times \text{EF} \times [\frac{\text{BR}}{\text{BW}}] \times \text{A} \times \text{CF})$$

Where:

Dose<sub>AIR</sub> = dose by inhalation ( $\text{mg}/\text{kg}\text{-day}$ ), per age group

C<sub>air</sub> = concentration of contaminant in air ( $\mu\text{g}/\text{m}^3$ )

EF = exposure frequency (number of days/365 days)

BR/BW = daily breathing rate normalized to body weight ( $\text{L}/\text{kg}\text{-day}$ )

A	=	inhalation absorption factor (default = 1)
CF	=	conversion factor (1x10 <sup>-6</sup> , µg to mg, L to m <sup>3</sup> )

The inhalation absorption factor (A) is a unitless factor that is only used if the cancer potency factor included a correction for absorption across the lung. The default value of 1 was used for this assessment. For residential receptors, the exposure frequency (EF) of 0.96 is used to represent 350 days per year to allow for a two-week period away from home each year (OEHHA, 2015). The 95<sup>th</sup> percentile daily breathing rates (BR/BW), exposure duration (ED), age sensitivity factors (ASFs), and fraction of time at home (FAH) for the various age groups are provided herein:

<u>Age Groups</u>	<u>BR/BW (L/kg-day)</u>	<u>ED</u>	<u>ASF</u>	<u>FAH</u>
Third trimester	361	0.25	10	0.85
0-2 age group	1,090	2	10	0.85

For construction analysis, the exposure duration spans the length of construction (e.g., 47 workdays, approximately 2 months). As the length of construction is less than 2 years, only the third trimester and 0-2 age bins apply to the construction analysis for the off-site residential receptors. Additionally, per OEHHA guidance a minimum exposure duration of 6 months (0.5-year) was used for the cancer risk calculations.

To represent the unique characteristics of high school student and preschool populations, the assessment employed the USEPA's guidance to develop viable dose estimates based on reasonable maximum exposure, defined as the "highest exposure that is reasonably expected to occur" for a given receptor population. Lifetime risk values for the population at Sunshine Shwetha Preschool and Daycare were adjusted to account for an exposure of 260 days per year (age 0 to 2 years). In addition, the calculated risk for children is multiplied by an ASF weighting factor of 10 (for children ages 0 to 2) to account for early life sensitivity to pollutant exposures (OEHHA, 2015). To calculate the overall cancer risk, the risk for each appropriate age group is calculated per the following equation:

$$\text{Cancer Risk}_{\text{AIR}} = \text{Dose}_{\text{AIR}} \times \text{CPF} \times \text{ASF} \times \text{FAH} \times \frac{\text{ED}}{\text{AT}}$$

Where:

Dose <sub>AIR</sub>	=	dose by inhalation (mg/kg-day), per age group
CPF	=	cancer potency factor, chemical-specific (mg/kg-day) <sup>-1</sup>
ASF	=	age sensitivity factor, per age group
FAH	=	fraction of time at home, per age group (for residential receptors only)
ED	=	exposure duration (years)
AT	=	averaging time period over which exposure duration is averaged (70 years)

The CPFs used in the assessment were obtained from OEHHA guidance. The excess lifetime cancer risks during the construction period to the maximally exposed resident were calculated based on the factors provided above. The cancer risks for each age group are summed to estimate the total cancer risk for each toxic chemical species. The final step converts the cancer risk in scientific notation to a whole number that

expresses the cancer risk in “chances per million” by multiplying the cancer risk by a factor of  $1 \times 10^6$  (i.e., 1 million).

The calculated results are provided in Appendix C.

### **1.5.2 Non-Carcinogenic Hazards**

An evaluation was also conducted of the potential non-cancer effects of chronic chemical exposures. Adverse health effects are evaluated by comparing the annual receptor level (flagpole) concentration of each chemical compound with the appropriate reference exposure limit (REL). Available RELs promulgated by OEHHA were considered in the assessment.

The hazard index approach was used to quantify non-carcinogenic impacts. The hazard index assumes that chronic sub-threshold exposures adversely affect a specific organ or organ system (toxicological endpoint). Target organs presented in regulatory guidance were used for each discrete chemical exposure. To calculate the hazard index, each chemical concentration or dose is divided by the appropriate toxicity value. This ratio is summed for compounds affecting the same toxicological endpoint. A health hazard is presumed to exist where the total equals or exceeds one.

The chronic hazard analysis for DPM is provided in Appendix C. The calculations contain the relevant exposure concentrations and corresponding reference dose values used in the evaluation of non-carcinogenic exposures.

### **1.5.3 Criteria Pollutants**

The BAAQMD has recently incorporated PM<sub>2.5</sub> into the District’s CEQA significance thresholds due to recent studies that show adverse health impacts from exposure to this pollutant. An incremental increase of greater than 0.3 µg/m<sup>3</sup> for the annual average PM<sub>2.5</sub> concentration is considered to be a significant impact.

## 1.6 CONSTRUCTION HRA RESULTS

The calculated results are provided in Appendix C and the results are summarized in Table 1.

TABLE 1. CONSTRUCTION RISK SUMMARY - UNMITIGATED

Receptor	Cancer Risk (per million)	Chronic Hazards	PM <sub>2.5</sub> ( $\mu\text{g}/\text{m}^3$ )
Maximum Exposed Receptor – Off-site Resident	0.1	0.0004	0.002
Sunshine Shwetha Preschool and Daycare	0.023	0.0001	0.0003
BAAQMD Threshold	10	1.0	0.30
<b>Exceeds Threshold?</b>	<b>No</b>	<b>No</b>	<b>No</b>

Note: Cancer risk calculated using 2015 OEHHA HRA guidance.

Cancer risk for the residential MER from project-related construction emissions was calculated to be 0.1 in a million, which would not exceed the 10 in a million significance threshold. In accordance with the latest 2015 OEHHA guidance, the calculated total cancer risk conservatively assumes that the risk for the residential MER consists of a pregnant woman in the third trimester that subsequently gives birth to an infant during the approximately 2-month construction period and calculated over a minimum 6-month exposure duration; therefore, all calculated residential risk values were multiplied by a factor of 10. In addition, it was conservatively assumed that the residents were outdoors 8 hours a day, 260 construction days per year and exposed to all of the daily construction emissions. The cancer risk for the maximum exposed preschool receptor was calculated to be 0.023 in a million which also would not exceed the significance threshold.

For non-carcinogenic effects, the chronic hazard index identified for each toxicological endpoint totaled less than one for all the off-site sensitive receptors. Therefore, chronic non-carcinogenic hazards are less than significant. For the residential MER, the maximum annual PM<sub>2.5</sub> concentration of 0.002  $\mu\text{g}/\text{m}^3$  would not exceed the BAAQMD significance threshold of 0.3 micrograms per cubic meter ( $\mu\text{g}/\text{m}^3$ ). Lastly, the preschool receptors maximum annual PM<sub>2.5</sub> concentration of 0.0003  $\mu\text{g}/\text{m}^3$  each would also not exceed the BAAQMD significance threshold. Therefore, the project would not expose off-site sensitive receptors to substantial concentrations of air pollutant emissions during construction and impacts would be *less than significant*.

inhalation rate (L/kg-day) <sup>1</sup>	361	1090
inhalation absorption factor	1	1
conversion factor (mg/ $\mu\text{g}$ ; $\text{m}^3/\text{L}$ )	1.0E-06	1.0E-06

Risk Calculation Factors:

age sensitivity factor	10	10
averaging time (years)	70	70
per million	1.0E+06	1.0E+06
fraction of time at home	0.85	0.85

exposure durations per age bin		exposure durations (year)	
Construction Year	Duration <sup>2</sup>	3rd Trimester	0 < 2 years
2022	0.18	0.25	0.25
Total	0.50	0.25	0.25

<sup>1</sup> Inhalation rate taken as the 95th percentile breathing rates (OEHHA, 2015)

<sup>2</sup> Construction duration determined for each year of construction to adjust receptor exposures to the exposure durations for each construction year (see App A - Construction Emissions). Since construction duration is less than 6 months, per OEHHA 2015 guidance health risks determined for 6 months (0.5 year).

<sup>3</sup> Chronic Hazards for DPM using the chronic reference exposure level (REL) for the Respiratory Toxicological Endpoint

**Table C3**  
**Day Care/High School MER Concentrations for Risk Calculations**

Contaminant ( a )	Source ( b )	Model Output <sup>1</sup> ( $\mu\text{g}/\text{m}^3$ ) ( c )	Emission Rates <sup>2</sup> ( g/s ) ( d )	MER Conc. ( $\mu\text{g}/\text{m}^3$ ) ( e )	Total MER Conc. Annual Average ( $\mu\text{g}/\text{m}^3$ ) ( f )	
<b>Preschool Receptors - Unmitigated</b>						
DPM	2022	On-Site Emissions	0.29	1.23E-03	3.53E-04	
		Truck Route	0.22	6.45E-07	1.39E-07	
Total DPM concentrations used for Cancer Risk and Chronic Hazard calculations						
PM <sub>2.5</sub>	2022	On-Site Emissions	0.29	1.13E-03	3.22E-04	
		Truck Route	0.22	6.45E-07	1.39E-07	
<b>Maximum Annual PM<sub>2.5</sub> Concentration      0.0003</b>						
Sunshine Shwetha Preschool/Daycare UTM coordinates: 627267.79 E, 4180176.84 N						

<sup>1</sup> Model Output at the MER based on unit emission rates for sources (1 g/s).

<sup>2</sup> Emission Rates from Emission Rate Calculations (Appendix A - Construction Emissions).

**Table C4**  
**Day Care/High School MER Health Risk Calculations**

Source	MER	Weight	Contaminant	URF	CPF	Dose (by age bin)		Carcinogenic Risks (by age bin)		Total Cancer Risk	Chronic Hazards <sup>3</sup>		
							0 < 2 years		0 < 2 years		REL	RESP	
	(a)	(b) (µg/m <sup>3</sup> )	(c)	(d)	(e) (µg/m <sup>3</sup> ) <sup>-1</sup>	(f) (mg/kg/day) <sup>-1</sup>	(g) (mg/kg-day)	(h) (mg/kg-day)	(i) per million	(k) per million	(m) per million	(n) (µg/m <sup>3</sup> )	(o)
<b>Preschool Receptors - Unmitigated</b>													
2022	On & Off Site	3.53E-04	1.00E+00	DPM	3.0E-04	1.1E+00		3.02E-07		2.26E-02	0.023	5.0E+00	7.06E-05
										Total	0.023		0.0001

Dose Exposure Factors:	exposure frequency (days/year)	260
	8-hour inhalation rate (L/kg-day) <sup>1</sup>	1200
	inhalation absorption factor	1
	conversion factor (mg/ $\mu$ g; m <sup>3</sup> /L)	1.0E-06

Risk Calculation Factors:	age sensitivity factor	10
	averaging time (years)	70
	per million	1.0E+06

exposure durations per age bin		exposure durations (year)	
Construction Year		Duration <sup>2</sup>	0 < 2 years
	2022	0.18	0.50
	Total	0.18	0.50

<sup>1</sup> Inhalation rate taken as the 8-hour 95th percentile breathing rates, Moderate Activity (OEHHA, 2015).

<sup>2</sup> Construction duration determined for each year of construction to adjust receptor exposures to the exposure durations for each construction year (see App A - Construction Emissions). Since construction duration is less than 6 months, per OEHHA 2015 guidance health risks determined for 6 months (0.5 year).
